1 Introduction & Motivation

Constructed languages—also called artificial languages, invented languages, planned languages, engineering languages, glossopoeia, or more simply as "conlangs" (Ball 2015)—are languages that are consciously and purposefully created for some intended use, usually being defined in antithesis to the spontaneous and organic method in which natural languages arise and develop (Sanders 2016). These variations of the term are often, but not always, used interchangeably, as linguists do not all agree upon a core term due to personal preferences (Adelman 2014), and there are sometimes differences in nuance depending on the context in which they appear. This thesis will mainly refer to them as constructed languages for simplicity.

The intended uses for which they are created can range broadly. Some are made specifically for fictional media, often seen in the genres of fantasy or science-fiction, with some more well-known examples being J. R. R. Tolkien's Elvish languages (e.g., Quenya, Sindarin, Nandorin) found in the world of Middle-earth in his writings, Marc Okrand's Klingon language from the Star Trek universe, and David J. Peter's Dothraki language used in George R. R. Martin's *A Song of Ice and Fire* novels along with their television adaptation, *Game of Thrones* (Jeffrey Punske (editor) 2020). Others are created to function as international auxiliary languages (IALs)—languages planned for the use of international and cross-cultural communication (Gobbo 2016). The most well-known example (based on estimated number of speakers) of these is Esperanto, created in the 19th Century by L. L. Zamenhof. Typically, constructed languages are distinguished and categorized based on these communicative functions. This will be discussed more comprehensively in section 2.

Despite being defined in contrast to one another, however, constructed and natural languages are not necessarily opposite to one another characteristically. Aside from their origins, the boundaries between the two are not always clear when analyzed in greater detail (Goodall 2022). For example, Schubert (1989) argues that some languages which are considered "natural" have some degree of artificiality, such as standardized written German and English differing from their spoken forms, and that the reverse is also true of some languages which are considered "artificial" because they draw from aspects of natural languages. As such, he believes human languages exist on a continuum of the two labels, rather than in the binary distinction—a view echoed by other linguists as well (Novikov 2022).

In many ways, the investigation into the disparity between these two kinds of languages overlaps with the broader debate regarding what constitutes a language. Central to this debate is the search for linguistic universals—

properties shared by all languages (Mairal and Gil 2006). The concept of universals in language is recognized as one of the most important areas of research in linguistics (Christiansen, Collins, and Edelman 2009) and has served as a foundation for much linguistic theory, especially in more recent history, stemming largely from the influential theories and works of Greenberg (Greenberg 1970) and Chomsky (Chomsky 1957; Cook and Newson 2007).

Analyzing their surface structures can reveal whether or not constructed languages adhere to the same linguistic conventions as their natural counterparts. If machine learning models fail to successfully distinguish between the two, it may reinforce the notion that these universals are present in all languages, regardless of origin. Conversely, the models succeeding may suggest the opposite. In short, the primary motivation behind this thesis is to contribute to this ongoing debate through the application of machine learning, and a hope to learn more about the fascinating genre of constructed languages.

1.1 Scope of Study & Research Question

The present work analyzes various linguistic features of both types of languages and seeks to make a comparison on the differences, if any exist, between them. More specifically, this study presents a binary classification task using decision tree and outlier detection models to determine if they can be distinguished from one another, based on the specific features examined and using a parallel dataset.

Because of the wide-ranging nature of conducting such a broad analysis, there will of course be many features left unconsidered or excluded, intentionally or otherwise. With this in mind and following the precedent set by other related research on this topic, the main focus for features relate to entropy, morphological complexity, and overall lexical diversity.

The following is a breakdown of the structure of this thesis from here onward: the next section provides relevant background information, including an overview on constructed languages and a comprehensive review of related literature that examines the prior theoretical groundwork laid for exploring linguistic similarities and differences between constructed and natural languages; section 3 covers in detail the methodology taken in this research, from an explanation of the data used to the various experiments performed; section 4 presents the results of the study and discussion of these follows in section 5; lastly, section 6 consists of a conclusion as well as elaboration for possible future work.

2 Background

The vast landscape of linguistic research comprises a myriad of literature delving into the intricacies of languages, both natural and constructed. As this paper is concerned with constructed languages in particular and possible distinctive properties they may have, this section begins with a brief overview of their history and development, which provides some relevant context. Following this is an overview of some related literature, which is relevant to understanding the motivation behind the various computational approaches I employ in my experiments.

2.1 History of Constructed Languages

Okrent (2009) states, "The history of invented languages is, for the most part, a history of failure." She may be justified in saying this, depending on one's definition of failure in this context. From past to present, the total number of constructed languages may be as high as a thousand (Libert 2016; Schubert 1989; Schubert et al. 2001), with hundreds proposed for the purpose of being IALs in Europe alone (Schubert et al. 2001). Yet of these, only Esperanto is commonly considered to be successful in achieving its creator's intended goal of world-wide use as an auxiliary language (or rather that it is by far the most successful), with very few others even coming close, having a conservative estimation of two million speakers (Okrent 2009).

While the construction of languages is possibly as old as human history, they typically were not written down and were limited to in-group communication (Gobbo 2016). The first documented endeavors came out of religious contexts and were likely used as secret languages, intentionally obscured and incomprehensible to lay people. In the 12th century, abbess Hildegard of Bingen described and recorded a lexicon for *Lingua Ignota*, a Latin name meaning "unknown language". While extensive documentation of it (i.e., a grammar) was never found, it possessed a semiotic system based on Latin, German, and Greek. Later in the 14th century, a group of Sufi mystics created *Balaibalan*, a language written in the Ottoman Turkish alphabet and which incorporated features of Persian, Turkish, and Arabic languages (Novikov 2022).

Interest in creating such languages picked up in the 17th century with the rise of so-called philosophical languages. In contrast to the last two, these languages were made to be more precise, less ambiguous, and better allow for philosophical reasoning (compared to natural language), such as by organizing world knowledge into hierarchies (Goodall 2022). Notable figures involved in making these include Francis Lodwick, Gottfried Leibniz, and John Wilkins, the latter of whose being arguably the most well-known and influ-

- (1) special > creature > distributively > substances > animate > species > sensitive > sanguineous > beasts > viviparous > clawed > rapacious > oblong-headed > European > terrestrial > big > docile

Figure 2.1: Wilson's expression of "dog" in his philosophical language (Goodall 2022)

ential. Wilkins created a system of semantic categorization, cataloging all concepts in the universe (Okrent 2009), and then published his proposed language (Wilkins 1968). An example of this hierarchal categorization can be seen in Figure 2.1.

In the 19th and 20th centuries the focus for language construction, especially in Europe, shifted to that of making international auxiliary languages (IALs) intended to better enable communication across language barriers, i.e., people who do not share a similar language (Goodall 2022). Notably, this means they were generally designed to resemble natural language, with choice exceptions being the simplification of certain linguistic features. The surge in need for IALs correlated with the increase in prevalence and accessibility regarding international travel and communication at the time. Such languages were also described as "neutral" (Large 1985), in the sense that individual advantages amongst speakers and learners would, theoretically, not exist due to IALs being second languages to everyone (Gobbo 2016). That being said, many of the most prominent examples (e.g., Volapük, Interlingua, Esperanto, Ido) are derived from the Indo-European language family (Novikov 2022; Goodall 2022), so such a description might not be apt. A more detailed explanation of each of the IALs used in this study is provided in Section 3.1

Finally, there exist constructed languages that have been made for experimental, artistic, literary, or fictional purposes. In contrast to IALs, these languages are not made with the intention of replacing existing languages for everyday communication. Instead, their creators want to push the boundaries of language, test scientific hypotheses like linguistic relativity, or create a world, as is the case for the fictional examples provided in Section 1. Some other examples in this category include Solresol, a language that uses musical notes; Láadan, a language designed to be inherently feminist (i.e. more capable of expressing the female experience); and Loglan, a self-described "logical" language whose morphology and syntax are based on predicate logic (Adelman 2014). Though it would be inaccurate to describe such languages as being only a recent invention, popularity in their conceptualization grew in the later part of the 20th century.

While all share the defining characteristic of having been purposefully created, the linguistic features of constructed languages (e.g., phonetic, morphological, syntactical, lexical, orthographic) can vary immensely depending on

factors such as, for example, their intended purpose for use or the other languages they draw from. An example of this was observed by Gobbo (2016) in secret languages, specifically their tendency to have more complicated features, such as morphological irregularities, "in order to preserve their secrecy." Contrast to this are IALs, which have the opposite tendency for the sake of ease of communication and second-language acquisition, reflected in commonly assigned features such as SVO word orders, head-initial relative clauses, fronted *wh*-phrases, and morphological regularity (Goodall 2022; Gobbo 2016). Section 2.2 further examines research focused on linguistic features of these languages.

In addition to this classification based on their intended communicative functions, i.e. as philosophical or international auxiliary languages, there are also taxonomies based on other criterion. For example, another frequently used distinction is that of *a priori* and *a posteriori* (Schreyer and Adger 2021; Gobbo 2008; Schubert 1989; Schubert et al. 2001; Novikov 2022; Adelman 2014; Tonkin 2015). Languages described as being *a priori* are structurally entirely new (Tonkin 2015) and not based on existing languages, whereas so-called *a posteriori* languages are the opposite, drawing from aspects of specific natural languages (Schreyer and Adger 2021). Gobbo (2008) also proposed the dichotomy of *exoteric* (secret) and *esoteric* (public) languages, derived from Bausani (1974). Similar to critiques regarding the distinction between constructed and natural, such dichotomies for categorizing constructed languages are also argued by some linguists to be more accurately described as scales instead, with many languages falling somewhere in the middle (Novikov 2022). A final noteworthy classification scheme often cited by other linguists comes from BLANKE (1989) in the form of three classes: project, semi-planned, and planned. In short, these correspond to a set of steps that a constructed language must go through before it can be considered a "real" language (Schubert et al. 2001).

A two-dimensional taxonomy for constructed languages containing several notable examples is shown in Figure 2.2 (Gobbo 2016).

2.2 Prior Studies

In contrast to the abundance in literature and cross-linguistic analyses done on natural languages, similar research which also includes constructed languages is relatively sparse. In particular, while there is research that analyzes specific instances of linguistic differences between certain natural and constructed languages, large-scale cross-linguistic studies which utilize computational methods to classify the two based on linguistic features are practically nonexistent. Consequently, the present study is a somewhat novel approach. However,

Figure 2.2: A taxonomy of constructed languages (Gobbo 2016)

there is precedent for this research and the specific features examined, as well as computational approaches used, which this section will describe.

As noted in the previous section, the creation of IALs often involved the intentional simplification of particular linguistic features to facilitate language acquisition, for instance having more regularity in their morphological systems. Intuitively, then, one would assume this translates to measurable differences in various aspects of linguistic complexity when compared to natural languages, which often have irregularities as a result of their development and evolution. When comparing Volapük and English, **Gobbo2016** concluded that

Much of the literature on constructed languages focuses on Esperanto specifically.

3 Methodology

In this section, I introduce the dataset for this paper and discuss the steps taken for preprocessing it, followed by discussing in detail the features examined along with the different methods involved in extracting them from the data, and finally the classification approaches and models employed on the feature set. A brief description of the various APIs and libraries used is also included in 3.3.

Since this study involves many different experiments and elements being analyzed, I will begin by explaining an overview of what all was done. The number of possible features and measurements of linguistic complexity which could be analyzed in such a study is extensive to say the least; however, the scope of this thesis focuses mainly on empirical measurements relating to lexical diversity, morphological complexity, and entropy, along with some others measurements which are commonplace to calculating linguistic complexity, and thus seemed appropriate to also include. More specifically, the features investigated are average word length, average sentence length, type-token ratio (TTR) of morphemes, average number of segmentations in a word, average number of forms per lemma, lexical TTR and the related moving-average type-token ratio (MATTR), lexical entropy, text entropy, and character and word distribution entropies. Once the features' values were calculated for each language, the task became that of classification and anomaly detection with three machine learning models: a one-class support vector machine (SVM), random forest, and decision tree. Lastly, the methods for evaluating the performances of these models are discussed, as is the Principal Component Analysis (PCA) performed on the data.

3.1 Data

In total, twenty-four languages are analyzed in this study. Six of these are constructed languages: Esperanto, Ido, Interlingua, Lingua Franca Nova, Volapük, and Kotava. The remaining eighteen are natural: German, English, Spanish, Polish, Vietnamese, Indonesian, Turkish, Tagalog, Hungarian, French, Finnish, Italian, Dutch, Occitan, Danish, Swedish, Afrikaans, and Icelandic.

For consistency, only languages which are written using the Latin alphabet (including the use of diacritics) were chosen. This is mainly because the constructed languages in the dataset all use Latin alphabets, so the selection of natural languages followed the same criteria. Moreover, it allows for more uniform cross-linguistic analysis of features which are sensitive (e.g. in the case of character entropy) to writing systems.

3.1.1 Constructed Languages in the Dataset

All of the constructed languages in the dataset are IALs and were chosen because of their availability in the Wikimedia dumps and having data which is comparable in size, allowing for their use as parallel texts. I will briefly introduce each of them in this section, explaining where they come from, some notable typological features they have, and how they compare to each other.

Esperanto, the most widely-spoken constructed language and considered by many to be the most successful (Gobbo 2008), was created in 1887 by Polish ophthalmologist L. L. Zamenhof. Zamenhof's goal was to create a neutral, easy-to-learn language that would facilitate international communication. Esperanto is a highly regular language, with consistent grammar and a simplified, phonetic spelling system. It draws its lexical roots and syntax primarily from Romance, Germanic, and Slavic languages (Gobbo 2008; Gobbo 2011), making it recognizable and familiar to speakers of many European languages, while also intentionally being made to have a comparatively simpler grammar that avoids some complexities found in natural languages, such as irregular verbs or noun cases. It also has a strong global community with speakers around the world, an array of written literature, and even a number of native speakers who learn it from birth—a distinguishing trait which sets it apart from other constructed languages (Goodall 2022). As a result of its success, Esperanto also serves as a direct influence for many other constructed languages that have come after it, one being Ido.

Ido is a reform of Esperanto that was proposed in 1907 by a group of linguists led by Louis Couturat, a French philosopher and mathematician, and in fact is an Esperanto word meaning "offspring" (Schubert et al. 2001). Its creators sought to address what they saw as imperfections in Esperanto, particularly those related to orthography and morphology. For instance, Ido avoids the use of the accusative case and reforms some Esperanto words to make them more universally recognizable. Overall, though, Ido still retains much of Esperanto's vocabulary and basic structure, and the two are mutually intelligible to a large extent (Goodall 2022; Schubert et al. 2001). Like most of the remaining constructed languages to be discussed in this section—with the exception of Volapük—Ido has small but a dedicated community of speakers and enthusiasts.

Interlingua was developed by the International Auxiliary Language Association (IALA) with the assistance of linguist Alexander Gode, officially being published in 1951. The idea behind Interlingua for it to most recognizable to the greatest number of people without requiring prior study (Goodall 2022), with most attention having been spent on its lexicon. The IALA's stated goal was to not so much create a new international language, but rather present a standardized international vocabulary (Large 1985) ("international" here

basically referring to Western Europe). It is largely derived from and resembles Romance languages (with lesser influence from Greek and Germanic languages) (Schubert et al. 2001). In fact, this intentional resemblance extends even to morphological irregularities such as allomorphy, with other irregularities also being introduced to the language to make it appear more natural (Goodall 2022), a contrast to other IALs like Esperanto.

Volapük was created in 1879 by Johann Martin Schleyer, a German Catholic priest who believed the language had been given to him by God. It features highly agglutinative structure and regular, yet complex, morphology. While being derived mainly from English, German, and Latin, roots in Volapük differ significantly to the point of being unrecognizable to speakers of these languages (Goodall 2022). Despite being argued to be the first successful constructed language due to its rise in popularity, having amassed a large number of supporters worldwide along with the formation of clubs and societies (Gobbo 2016), various issues regarding its complexity led to a rapid decline and eventual fall from usage in favor of Esperanto.

Lingua Franca Nova, also abbreviated as LFN, is a relatively recent constructed language created by linguist C. George Boeree in 1998. Its lexicon is based mainly on Romance languages, specifically French, Italian, Portuguese, Spanish, and Catalan, while its grammar is based on Romance creole languages (Pawlas and Paradowski 2020). In particular, inspiration came from the similarly-named Mediterranean Lingua Franca, a pidgin that developed for trade in the Mediterranean basin and was used from the 11th to 18th centuries, as well as from other creoles, such as Haitian Creole. It can be written in both Latin and Cyrillic scripts, though this dataset only contains the former.

The last constructed language used is Kotava. Created by Staren Fetcey in 1978, Kotava stands out in this dataset as being a unique attempt at creating a culturally neutral *a priori* language, free from any biases or influences of existing languages, especially with regards to lexicon, and based on a philosophy of linguistic egalitarianism. Its morphology, syntax, and phonetic system are all intentionally made to be simplified and regular.

Conlang	Source Languages/Families
Esperanto	Romance, Germanic, Slavic
Interlingua	Romance
Lingua Franca Nova	Romance
Volapük	Germanic
Kotava	N/A
Ido	Romance, Germanic, Slavic

Table 3.1: Constructed languages used in the study, together with their main respective source languages from which they were designed.

Finally, it is worth drawing attention to the fact that each of these lan-

guages were constructed mainly from various European languages, with the exception of Kotava. Consequently, this may influence the models performing classification and be visible in the results. This will be explored in greater detail later in Section 5.

Table 3.1 shows the dataset’s constructed languages together with the main source languages they draw from (with *N/A* for Kotava meaning *not applicable*). Note, however, that this is not an exhaustive list of all of their language influences.

3.1.2 Natural Languages in the Dataset

The natural languages included in this study represent a broad spectrum of linguistic diversity, comprising a variety of families, geographic regions, and typological features. Although this representation is not necessarily equal in distribution, it is meant to serve as a contrast to the constructed languages in the dataset, which lack a similar extent of variety due to overwhelmingly having the same source languages. However, rather than delving into the same level of details for each of the eighteen languages here as I did for the constructed ones, I will instead introduce them by focusing mostly on their collective significance and summarizing some of their relevant linguistic traits.

The language families represented are Austroasiatic, Austronesian, Turkic, Uralic, and Indo-European, with the latter being both the largest worldwide based on number of speakers and the most represented in the dataset (12 out of the 18 natural languages). While language families are defined through their collective sharing of linguistic features and common ancestors, they also contain some degrees of in-group variance as a result of evolution over time and are thus further divided into different subgroups accordingly. For the Indo-European languages in the dataset, English, German, Dutch, Afrikaans, Swedish, Icelandic, and Danish all belong to the Germanic branch. Likewise, Italian, Spanish, French, and Occitan are in the Romance languages, and Polish is Slavic.

Hungarian and Finnish are two of the most widely-spoken Uralic languages, so their inclusion provides a representative sample of their group.

The remaining languages were included in order to have more variety beyond only Europe. These are Tagalog and Indonesian (Austronesian), Vietnamese (Austroasiatic), and Turkish (Turkic).

In terms of morphological typology,

3.1.3 Wikimedia

The data for this thesis comes from Wikimedia dump files. Wikimedia is a global movement and community founded on shared values, whose goal is to provide free and openly accessible information to everyone in the form of massive collaborative projects (which include, among others, the widely-used Wikipedia and Wiktionary). For a large, cross-linguistic study, massive databases with open-access make for an ideal source for corpora. Most importantly, the projects are multilingual, meaning data is available in a considerable number of different languages—including several constructed ones. This allows for composing a set of corpora which is adequately parallel to each other and from the same domain. Additional constructed languages which are also available from the dumps—but were not included in the present study due to having a much smaller amount of data—are Novial, Interlingue, and Lojban.

The dump files provide detailed, archived snapshots of the content from Wiki repositories for a specified point in time and are available in different formats. All dumps used were XML-formatted and from the 2024-07-01 archive, containing articles together with their metadata¹. It is also worth mentioning here that there are some drawbacks to using these dumps for the present study. The files sizes vary considerably depending on the language, with the largest being roughly 22 gigabytes (English) and the smallest around 4 megabytes (Lingua Franca Nova), meaning all files do not contain the exact same articles. Additionally, the open and collaborative nature of Wikimedia means the articles are often authored by a multitude of different people, which can result in inconsistencies in the texts, such as with writing style. Similarly, it may also produce an imbalance in the amount of information provided across languages, with the same article in one language being considerably more detailed than in another, and inconsistent or low-quality translations, as Novikov (2022) noted to be the case for Wikipedia articles in Volapük. Thus, while Wikimedia was decided as the best available option for the task at hand, there are some unfavorable aspects of using it which may influence the results; this will be discussed more in Section 5.

3.2 Data Preprocessing

Preprocessing text data is essential for natural language processing (NLP) tasks, and since I essentially had to compile my own corpora for this study, meticulous effort was made to thoroughly clean all of the texts and obtain as close to a set of parallel data as possible.

Text data was first extracted from the Wikimedia XML-formatted dump

¹<https://dumps.wikimedia.org/backup-index.html>

files with the use of WikiExtractor², a Python script (Attardi 2015) that I adapted by adding a limit to the number of articles in order to make extraction of the largest of the files (English in particular) less demanding and quicker. The output is a simple text file, which is a much easier format to clean and work with.

I then used several regular expressions to remove general, unnecessary text from each file such as page titles, section headers, links, fragments, HTML tags, braces, and all other non-alphabet symbols aside from periods. This also includes the removal of parentheses and their contents. The text was then made all lowercase and split by the periods—while also attempting to account for abbreviations—to make separate sentences. This was done mainly to enable more accurate measurement of entropy later.

Following this, foreign symbols (i.e., characters not part of a particular language’s alphabet) were removed for each text/language, as occasionally proper nouns, loanwords, etc. would appear in the text, which would also affect measurements of entropy, in addition to morphological segmentation and analysis. To give an example of this, there is no letter ‘h’ in Kotava, but this would sometimes be used in proper nouns such as ‘Hiroshima’. After the text is cleaned, the remaining word left behind is ‘irosima’.

Finally, each text file was truncated according to the file size of the smallest corpus, LFN, so as to have similar lengths. This was calculated based on number of words, with the limit being 630000 (since this is roughly the number of words remaining in the LFN text file after cleaning), and while preserving complete sentences. Sentences containing only one word were also removed. The end result of pre-processing was a single text file corresponding to each language, with each line in the file being a single sentence. The corpora with the smallest and largest number of words is Kotava and Danish/Volapük at 617400 and 629999 words, respectively. For number of sentences, the smallest and largest corpora are Vietnamese and Volapük at 21115 and 55920 sentences, respectively. For a breakdown of these size for each language’s text after pre-processing, refer to Table 8.1.

3.3 Libraries and APIs

Several libraries and APIs were used in both the feature extraction and classification parts of the study, and the most important of these will be briefly introduced here. In the field of machine learning, two of the most popular model frameworks used are PYTORCH and TENSORFLOW, which are interacted with via the TORCH and KERAS APIs, respectively. Aside from some relatively minor differences (e.g., the syntax of their code and performance

²GitHub repository for WikiExtractor: <https://github.com/attardi/wikiextractor>

optimization), they share a lot of similarities and are typically used according to personal preference. In the context of this paper, these frameworks are used for calculating some of the entropy values from the corpora. In addition to libraries used for constructing the model architectures, there are also ones used for the data itself. Arguably the most fundamental for this is `NUMPY`, which stands for Numerical Python and is used to accomplish extremely fast and efficient computation of arrays. Other essential libraries include `PANDAS`, used for data manipulation and analysis, and `MATPLOTLIB`, used for visualizing data and plotting model results. Lastly, `SCIKIT-LEARN` provides a wide range of tools for machine learning algorithms, data preprocessing, and model evaluation—as well as computation, thanks to it being built on top of `NUMPY`. The models I used for classification (i.e., One-Class SVM, Random Forest, Decision Tree) as well as PCA come from this library. Altogether, these libraries are often used in tandem due to integrating so well with one another.

3.4 Feature Extraction

A crucial step in many NLP tasks is feature extraction. Before training the classifiers for anomaly detection,

3.4.1 Lexical Diversity

A popular way of measuring lexical diversity is with TTR, given by the formula

$$TTR = \frac{\sum_{i=1}^n \delta(w_i)}{n}$$

where δ corresponds to

A glaring issue with TTR, however, is that it can vary widely based on a text's length. The longer a particular text, the higher the likelihood of repetition occurring. There have been several solutions proposed to address this issue, one being MATTR. MATTR is given in the formula

$$MATTR_i = \frac{TTR_1 + TTR_2 + \dots + TTR_i}{i}$$

3.4.2 Morphological Complexity

The morphological systems of each language were analyzed using Morfessor,

3.4.3 Entropy

In information science, entropy means...

The entropy was calculated for the character and word distributions in each of the corpora, given by the following formula:

$$H = - \sum_{i=1}^n p_i \log_2 p_i$$

For text entropy, a character-level long short-term memory (LSTM) model built with PYTORCH was used.³

3.4.4 PCA

Principal Component Analysis was performed for dimensionality reduction.

3.5 Classification

3.5.1 Decision Tree

Decision Tree Classifier...

3.5.2 Random Forest

3.5.3 One-Class SVM

One-Class SVMs are a special kind of SVMs used in the domain of anomaly detection. While similar to one another, classic SVMs separate two classes using a hyperplane with the largest possible margin. In contrast to this, One-Class SVMs...Rather than training on an entire dataset containing two classes as with classic SVMs, these models train exclusively on the majority class, also called the "normal" class. After training,

Standardization is given by the formula

$$X' = \frac{X - \mu}{\sigma}$$

where μ is mean and σ is the standard deviation.

3.6 Evaluation of Classifiers

³Model adapted from <https://github.com/LeanManager/NLP-PyTorch/blob/master/Character-Level%20LSTM%20with%20PyTorch.ipynb>

Figure 4.1: Principal Component Analysis on TTR, MATTR, Word and Char Distribution Entropy

4 Results

This section reports the results of each of the methods implemented.

4.1 Results of Lexical Diversity

4.2 Results of Morphological Segmentation

4.3 Results of Feature Extraction

4.4 Results of PCA

A script was used to increase readability of the text in the graph⁴.

4.5 Results of One-Class SVM

4.6 Results of Decision Tree

4.7 Results of Random Forest

5 Discussion

6 Conclusion

6.1 Future Work

The research presented in this thesis is far from encompassing all there is to the topic of defining language, and distinguishing between constructed and natural language. At present, this is an area of research with ample room for potential development.

Limiting factors: number of languages and which languages/language families, lack of real parallel corpora, problems associated with low-resource languages, relatively narrow scope of experimentation,

7 Acknowledgments

I would like to thank
